

SCHOOL OF MEDICINE

CASE WESTERN RESERVE UNIVERSITY

MASTER OF SCIENCE IN ANESTHESIA PROGRAM

Learning Objectives:

- ✓ The learner will be able to define a bronchospasm.
- ✓ The learner will be able to recognize situations in which there is an increased risk of bronchospasm and implement methods to decrease this risk.
- ✓ The learner will be able to identify perioperative events indicative of a bronchospasm and apply appropriate interventions in a step-wise manner based on severity.

Defining Bronchospasm¹

Contraction of bronchial smooth muscle that results in reversible narrowing of medium and small airways.

Fast facts⁷: Incidence: ~0.2% - GA, ~6% - asthmatics // *Occurrence:* most frequent = induction // *How:* mechanical or pharmacological // Quick recognition avoid complications \rightarrow \downarrow SaO2, \uparrow PaCO2, hypotension (\uparrow ITP), barotrauma, CV

Physiology²

- Bronchial tone maintained by PNS
 - PNS overactive/ \uparrow cGMP \rightarrow vagal activation (sensitive to histamine, noxious stimuli) \rightarrow bronchoconstriction
 - Noxious stimuli: cold air, inhaled airway irritants, airway manipulation⁶ (especially when airway reflexes are not adequately depressed)
- Chemical mediators/Immune mediated degradation of bronchial mast cells \rightarrow bronchoconstriction
 - Histamine, bradykinin, leukotriene, prostaglandins, platelet activating factor

Presenting Characteristics¹

- 个 PIP
- Wheezing \rightarrow usually heard on exhalation
 - Severe \rightarrow possible absence of gas movement = no audible wheezing
- Upward sloping EtCO2 waveform (figure 2)
 - Severe \rightarrow may be diminished or absent
- \downarrow PaO2 and SpO2
- \downarrow TV, inability to achieve adequate TV's despite mechanical ventilation parameters (figure 1)

Expiratory obstruction

Time

- ↑ PaCO2 and EtCO2 gradient
- Poor lung compliance/difficult mask ventilation
- Hypotension

delivered, with an increase in pressure. This results in the pressure volume loop being shifted to the right and flattened. In pressure control ventilation (B), the stiffness of the lung results in a decreased tidal volume, without a change in the pressure (because that is the ventilator setpoint)

Anesthetic Management of a Severe Bronchospasm

Morgan Davis SAA2 // Mentor: Alex Castillo CAA - MGUH

- 100% FiO2
- Quickly assess compliance with manual ventilation. Call for help.
 - Mechanical ventilation \rightarrow adjust RR and I:E as needed (maximize E) - avoid auto-PEEP (hyperinflation/air trapping)
- Differentials/Verify diagnosis
 - Auscultate, verify ETT position/patency, soft suction ETT \rightarrow clear potential obstruction, \checkmark pilot balloon
 - Aspiration, kinked/obstructed ETT, pneumothorax, foreign body, amniotic fluid embolism, pulmonary edema, PE, endobronchial intubation (mainstem), anaphylaxis, breath stacking, carcinoid syndrome
- Mild bronchospasm:
 - Increase anesthetic depth: \uparrow concentration of non-pungent gas, propofol, opioids, ketamine²
 - B2 agonist: albuterol 4-8 puffs (repeat as needed) note: manual + pressure breaths to ensure it's getting to lungs
- Combo therapy: Ipratropium bromide + albuterol
- Moderate to severe bronchospasm:
 - Add to differentials: silent aspiration possible \rightarrow suction ETT

> Pt: 53 y/o M, 139 kg presenting for bilateral lower extremity debridement > PMHx: DM2, CAD, PVD w/stents, HTN (poorly controlled/on b-blockers), HLD, HFpEF, CVA

- Plan: GA/ETT (CMAC in room), prone, ext
- \succ Timeline of Events: In room 2 V/50 F \rightarrow surgeon \rightarrow induction with 50 F/100 lido/2 prop \rightarrow bag mask $\checkmark \rightarrow$ 50 roc \rightarrow bag mas difficult \rightarrow intubation 1- DL \rightarrow intubation CMAC \rightarrow suctioned secretions, pt light \rightarrow mask + \uparrow depth \rightarrow intubation 3 - CMAC placement = wheezy + mainstem \rightarrow pull l tube $\rightarrow \uparrow$ PIP, \downarrow SpO2, poor compliance bronchospasm high on differential \rightarrow seve bronchospasm management \rightarrow called for after interventions not improving SpO2 -> a-line, increased epi dose \rightarrow case cancele stable \rightarrow transport to ICU intubated \rightarrow cl call airway emergency in ICU \rightarrow CXR
- **Tx:** 100% FiO2, manual vent, deepened anesthetic (sevo, propofol, rocuronium), bronchodilator therapy - albuterol + epi,
- ICU: Neb tx, corticosteroid: Solu-Med What went wrong: appropriate anestheti depth not achieved before intubation (\uparrow of propofol and rocuronium, bag mask wi on), didn't optimize initial intubation atte with CMAC, could have treated HTN earlie esmolol?³, optimize transport, verify EtCO

Bronchospasm Management¹

• Bronchospasm not resolving \rightarrow SEVERE

- Inform surgeon
- B2-agonists: albuterol 4-8 puffs
- IV bronchodilator therapy:
 - Epinephrine IV \rightarrow 0.1 mcg/kg bolus then titrate infusion² of 5-20 ng/kg/min if not resolving
 - MgSO4 IV \rightarrow 2g
- Corticosteroids \rightarrow methylprednisolone 125 mg IV bolus
- Stop surgical stimulation
- Cancel case or proceed? Can we extubate?²
 - No \rightarrow Transfer to ICU
 - Yes \rightarrow optimize, lidocaine 1.5 mg/kg IV, albuterol puffs via ETT, continue epi if needed, deep extubation?², continue bronchodilator therapy in PACU
- Heliox (lower density = improve airflow)
